$$X * (Y+Z) = (x*Y) + (x*Z)$$

Mathematical Algebra

An algebra is a mathematical system consisting of

- Operands variables or values from which new values can be constructed.
- Operators symbols denoting procedures that construct new values from the given values.

Definition

Algebra

Relational

Relational Algebra

A **relational algebra** is an algebra system for SQL queries consisting of

- Operands relations/tables.
- Operators transformations from one or more input relations into one output relations.

Note

Relational algebra is an **imperative** query language. It forms the mathematical foundation of relational database engines and are used to specify how data can be retrieved.

Relational algebra is essential to understanding how database queries are **procesed** and **optimized**.

▶ Algebra

Definition Relational

*Operators*Operations

Sample Data

Algebra

Operators

Relational Algebra Operators

The main algebraic operators are the following.

Unary Operation	S	ymbol	Set Operation	Symbol	Binary Operation	Symbol
Selection	S	(0)	Union	U	Cross Product	(×
Projection	P	π	Intersection	n /	Inner/Natural Join) ×
Renaming	R	ρ	Set Difference	(-)	Outer Join	MMM

Other algebraic system adds more operators but we will not use them.

Relational algebra is based on **relations**. In turn, relation is based on **set**. So, there is **no duplicate row** in relational algebra. This is **slightly different** from SQL.

multiset/ban

Algebra **▶** Operations Logical Relational Sample Data

Operations

Logical

Propositional Logic

The model semantics of **propositional logic** is defined by the truth tables of connectives: **conjunction** (\wedge),

disjunction (\vee), and negation (\neg)*.

	uisjunct		id Hegatio)	and	٥٢	T.

Relational

Sample Data

Operations

Relational

Relational Operator

We use the standard relational operators: equal to (=), not equal to (\neq), less/greater than (</>/>), and less/greater than or equal to (\leq / \geq)*.

Note

The meaning of the operation follows the usual meaning. For **TEXT**, the **S1** < **S2** means that **S1** is *lexicographically* smaller than **S2**.

To avoid issues with precedence, add parentheses as necessary.

^{*}Without **NULL** value, we do not have to worry about the problem with = and ≠ operators.

Algebra

Why Renaming?

Set

Product Join

Renaming

Why Renaming?

SELECT-FROM-WHERE + Dot Notation

For good practice, we require all tables to always be renamed in SQL. This notation is now also available in relational algebra.

We also allow dot notation r.attr to simplify the writing.

```
SELECT DISTINCT r.attr π[r.attr](
FROM rel r σ[c](
WHERE c; ρ(rel, r)))
```

Note

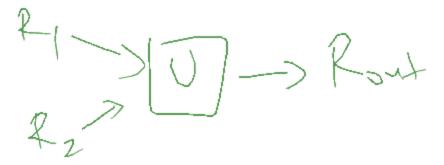

Other source of relational algebra (even from past semesters) may use different convention and/or notation. Our notation is chosen to simplify reading and writing by adhering closer to good SQL notation.

Selection Projection Renaming

Set

Examples

Example #1

Find the different pizza sold by both Bella Italia and Desert Diner.

Code

```
Q1 := π[pizza](σ[rname = 'Bella Italia'](sells))
Q2 := π[pizza](σ[rname = 'Desert Diner'](sells))
Q1 n Q2
```

```
SELECT s.pizza FROM sells s
WHERE s.rname = 'Bella Italia'
INTERSECT
SELECT s.pizza FROM sells s
WHERE s.rname = 'Desert Diner';
```

Note

We also add := similar to an **assignment** to break up complex queries to simpler queries. The **temporary** relation can be used for subsequent algebraic operation.

Result

Join

Operator

Join

 $R_1 \bowtie_{[c]} R_2$ is simply **defined** as $\sigma_{[c]}(R_1 \times R_2)$. In other words, we include only tuples that **satisfies the condition** \boldsymbol{c} after the cross product.

Note

SELECT-FROM-WHERE

```
SELECT DISTINCT a1, a2, a3, ...

FROM r1, r2, r3, ...

WHERE c; -- c = c1 AND c2
```

```
π[a1, a2, a3, ...](
σ[c](r1 x r2 x r3 x ...)
) # c = c1 Λ c2
```

Inner Join

the condition c1 uses attributes from c3.

```
SELECT DISTINCT a1, a2, a3, ...

FROM r1 JOIN r2 ON c1

JOIN r3 ON c2;
```

The two versions are <u>almost equivalent</u>. The only exception is when

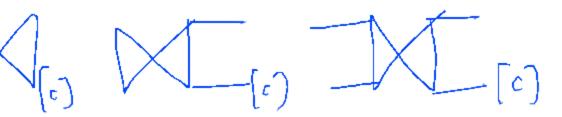

```
π[a1, a2, a3, ...](
    r1 ⋈[c1] r2 ⋈[c2] r3
) # (r1 ⋈[c1] r2) ⋈[c2] r3
```

Examples

Operator

Join

 $R_1 \bowtie_{[c]} R_2$ is simply **defined** as $\sigma_{[c]}(R_1 \times R_2)$. In other words, we include only tuples that **satisfies the condition** \boldsymbol{c} after the cross product.

Variants

Natural Join

If we exclude the condition c, the operator becomes the **natural join operator** (i.e., \bowtie). For example, $R_1 \bowtie R_2$.

Outer Join

We also have **left** $(\bowtie_{[c]})$, **right** $(\bowtie_{[c]})$, and **full** $(\bowtie_{[c]})$ **outer join** variants that depends on the condition \boldsymbol{c} .

Natural

There is also **natural** variant by omitting **c**.
